COVID-19 Spread (Part II)

- I'm not an epidemiologist, doctor, or any kind of expert on the subject. I just look at the numbers.
- This was originally written on Sunday March 22nd. Since then, I've updated the numbers and added updates at the end of the post.

In Part I, I built an exponential model using data between March 2 and March 15, then continued to add daily numbers to see how that model tracked:

Initi ally, the num ber of case S dou bled ever У 2.7 day S, pred ictin g alm ost 160 case s by the end of Satu rday Mar ch 21, but sinc е Thur sda

y, the

Growth Factor

There's a ratio involving three data points that's useful to track how "fast" the exponential grows. It's easier to explain with an example, so suppose we had three days like this:

Day	# of Cases	New Cases	Growth Factor	now ca	sos is itsolf increasing	a oach day y	which means we are s	till in
Day1	[100] grow	in ractor >	L , the number of	new ca	פבי וז ונזבוו וווכופמצווונ	y each day, v	willen means we are s	LIII III

Day #10fe@ases Niewp@ases Growth Factor To calculate the growth factor: Day2 If the growth factor = 1, then the number of cases is growing at a constant rate (same amount each day).

Day3 Isos is the noddle of the positic Curve (more on that soon).

Take the number of new cases from one day to the next (10 new cases from Day 1 to Day

If the growth factor < 1, then the infection rate is levelling of new cases from Day 2 to Day 3)

- If the **growth factor = 0**, then the epidemic is over.
- Then, take the ratio between new cases (20 $\div 10 = 2$)

e are the num ber of case s in Can ada with the calc ulat ed gro wth fact ors:

to ima gine that testi ng labs are lagg ing а few day S behi nd and that they '|| som etim es be able to repo rt mor е resu lts one day and less the next

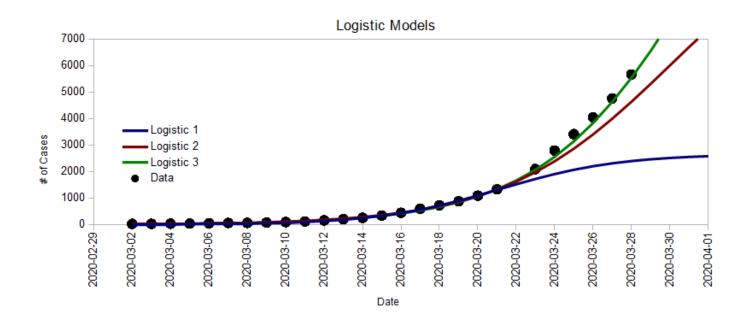

We don't have an accurate picture of the world here so it's hard to make any kind of hard predictions. Never-theless, as of March 21, there seemed to be a loosely decreasing pattern:

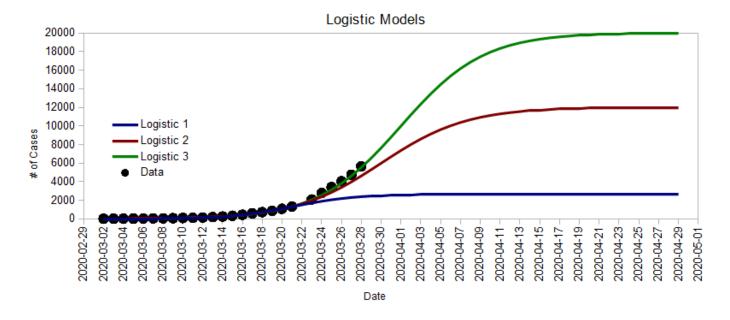

Overall, the growth factor is mostly above 1 (in the exponential phase), but it looks like we might be on track to reach 1 by the end of the month (end of exponential phase). If that's the case, and if we continue to implement measures to slow the down the spread, then we'll be in a better position to estimate the final outcome by the end of the month. Here's why.

The Logistic Curve

In Part I, we saw that very different Logistic Curves can fit the current data, and that there's really no way of knowing which path we're on yet. Here they are again:

- Logistic 1 was the very best case scenario (as of March 22) where the total number will be double of what it is today. This assumes that the growth factor reached 1 yesterday (March 21), which it hasn't. But we're way passed that now.
- Logistic 2 is an optimistic scenario where the total number reaches 12,000 and the growth factor reaches 1 on March 30st.
- Logistic 3 is a very likely scenario where the total number reaches 20,000 and the growth factor reaches 1 on April 1st. This is **not** a worst case scenario. Things could be much worse (look at Italy).

Logistic 1	Logistic 2	Logistic 3	
$$N = \frac{2660}{1 + e^{-0.32(t - e^{-0.32})}}$	$$N = \frac{12000}{1 + e^{-0.232}(t)}$	$$N = \frac{20000}{1 + e^{-0.24(t - e^{-0.24(t $	
21.1)}}\$\$	- 30)}}\$\$	32)}}\$\$	

Here are a few things to know about the Logistic Curve. In the middle:

- The curve is flat like a straight line, which indicates that the growth rate is constant.
- This means that the growth factor is 1 (by definition)
- It also happens that this is the halfway point in terms of total number of cases.

So once we reach that point, we'll be able to get a better estimate of where we'll end up. Until then, things are still very much in the air.

March 28th Update

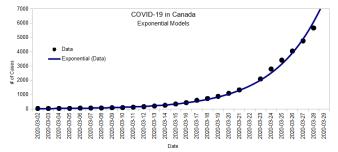

A lot happened this week:

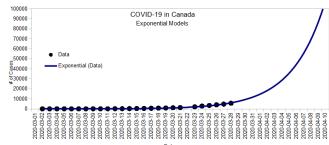

• BC seems to be dropping the ball on testing. Their reported numbers are proportionally much lower than Quebec and Ontario and the messaging is that we might finally be "flattening the curve". However, it could simply be that we are not testing enough and are way behind on reporting results. On a personal note, I finally got my result yesterday (negative): three weeks after getting tested!

The

• Quebec went the opposite way, increasing their testing and finding a lot more cases.

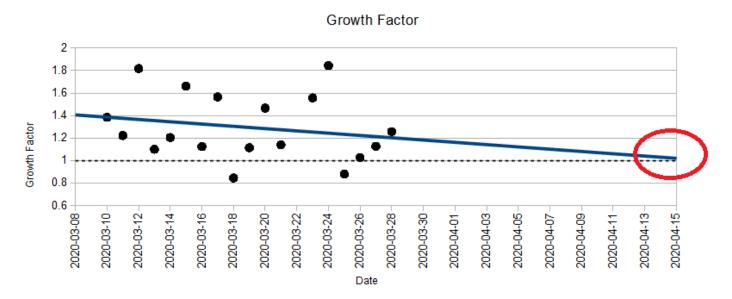

Over all, it looks like we are back on the exponential curve with an overall doubling time of 3.1 days:

Gro wth Fact or also see ms to sup port this as it is bare ly decr easi ng. Agai n, a Gro wth Fact or of 1 mea ns that we coul d be at the halfway mar k. As long as it's abo ve 1, we don' t

kno w...

Over a week ago, back when we only had 342 cases, the model (at the time) predicted we were about two weeks behind Italy (which had 26,000 then).

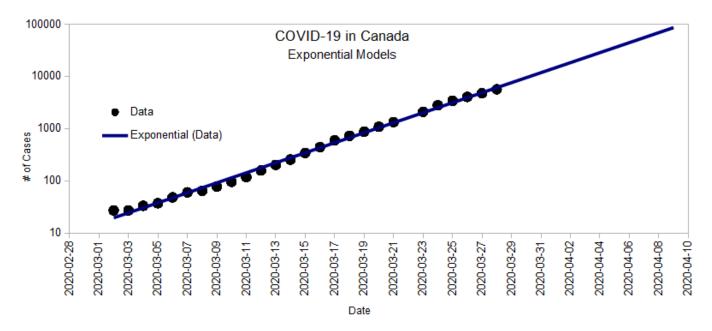

The updated model (doubling every 3.1 days) predicts that we are about 12 days behind Italy (with now has over 92,000 cases). Whatever we have been doing is either not working or we are not seeing the effects yet.

According to the CBC from March 25th:

"Dix and provincial health officer Dr. Bonnie Henry both said they are optimistic B.C. isn't following the same path as countries like Italy that have seen their healthcare systems overwhelmed by huge spikes in hospitalizations and deaths."

Country-wide, the numbers disagree. We have about two weeks behind Italy since the beginning of March. Province-wide, the numbers do look better, but it could well be because we are not testing as much as other provinces like Quebec and Ontario. There are no reasons to be optimistic about being on a different path.

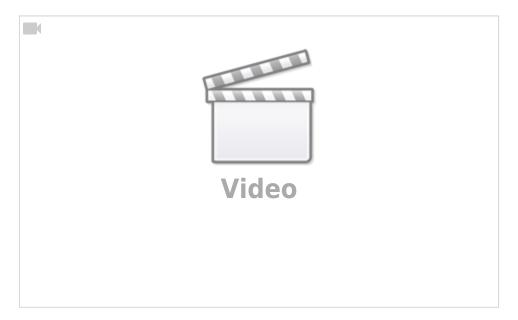

Here's a different way to look at the exponential curve when the number of cases is presented as a multiple of 10 on the vertical axis (called a logarithmic scale):

If we stay on that line, we'll reach 100,000 cases by April 10th!

Cleaning Groceries

Here's a video shared by the Mid Island Radio Group:

Other Models

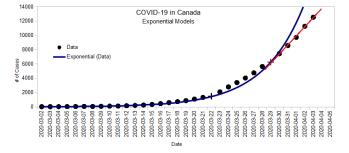

Compartmental Models are popular such as the SEIR (Susceptible, Exposed, Infected, Recovered) Model. https://en.wikipedia.org/wiki/Compartmental models in epidemiology#The SEIR model

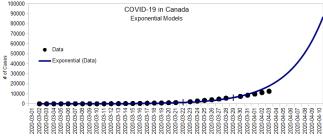

Kaggle has a modelling competition which has some good data sets. You need to use a Google ID to access this (I

think since Google brought Kaggle a few years ago). https://www.kaggle.com/c/covid19-global-forecasting-week-3

April 3rd Update

Hard to believe that a month ago, there was only 27 reported cases in Canada (compared to 12,549 cases today). It looks like BC is still vastly under testing so the actual numbers are probably much higher than they appear to be. However, looking at what's reported, it looks like we *could* be nearing the halfway mark:

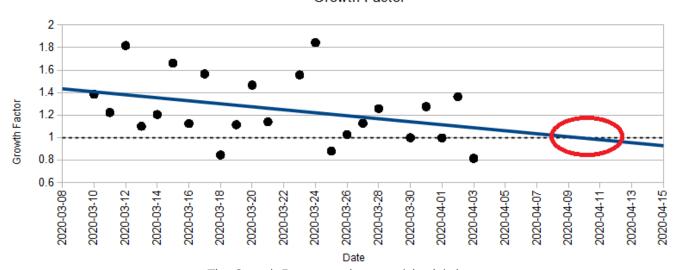

For the last wee k, the infe ctio n rate see ms to be flatt er than it has bee n.

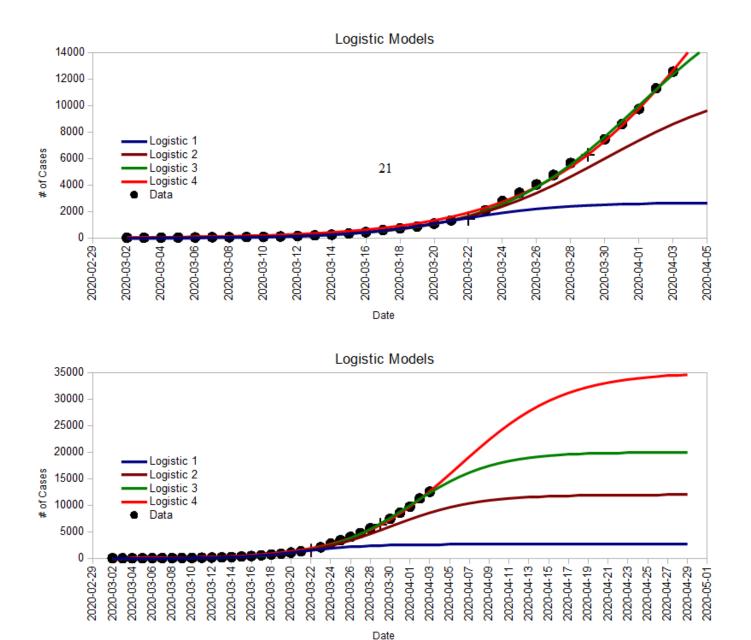

Last update: 2020/04/12 09:34

Growth Factor

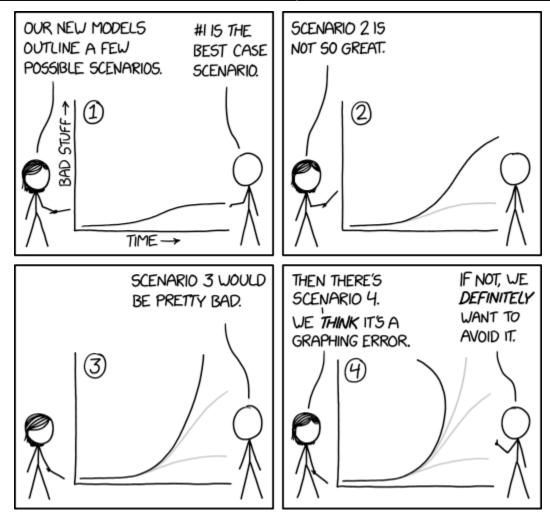

The Growth Factor continues to (slowly) decrease.

With the same physical distancing measures in place, it looks like we could see between 20,000 and 35,000 cases. But the future is still highly unpredictable precisely because it is up to us.

I've also said a few times that BC is way behind on testing and that the numbers we see are vast underestimates. This CBC article, Why COVID-19 testing varies so much across Canada, dives into this issue somewhat. It would be nice if, in addition to the number of new cases reported, each province also had to report the number of tests that were analyzed that day. It would give us a much better sense of how everyone is doing. For example, if Quebec is testing 10 times more than BC is, it's not surprising they are finding more cases. That's just an example because I don't know how much more they are testing. If anyone finds that information somewhere, please share it here!

On a lighter note, xkcd puts this whole post into context:

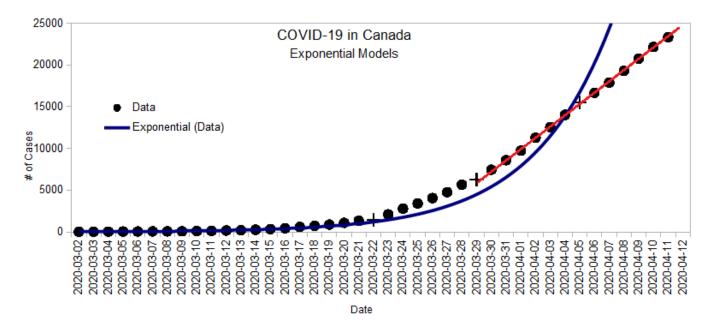

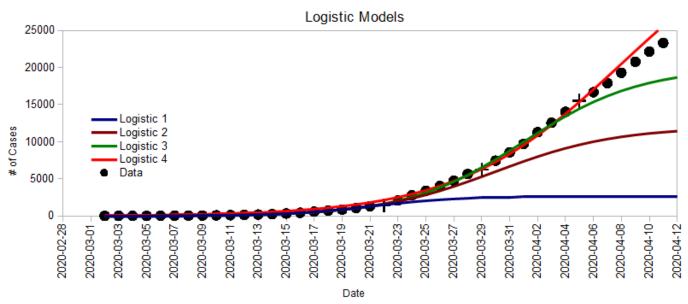

"Remember, models aren't for you telling facts, they're for exploring dynamics.

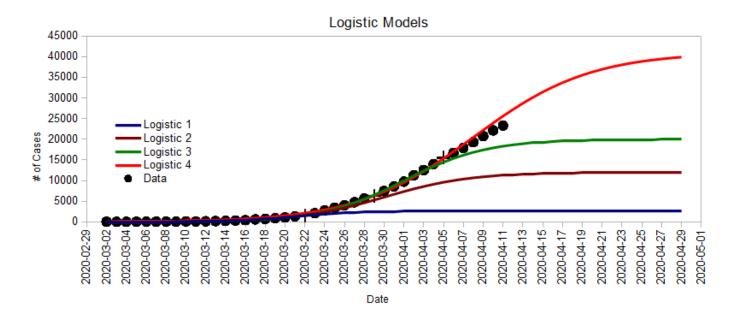

This model apparently explores time travel."

April 12th Update

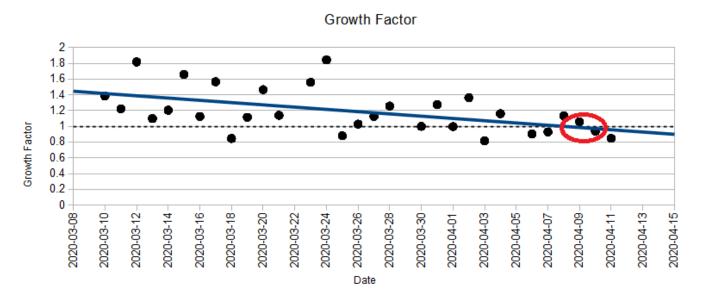

It's been over a week since the last update and according to the numbers, it looks like we are off the Exponential curve and into the linear growth middle section of the Logistic curve:

The calculated Growth Factor also seems to have dipped below 1:

Again, recall that:

- If the **growth factor > 1**, the number of new cases is itself increasing each day, which means we are still in the exponential phase.
- If the **growth factor = 1**, then the number of cases is growing at a constant rate (same amount each day). This is the middle of the Logistic Curve (more on that soon).
- If the **growth factor < 1**, then the infection rate is levelling off.
- If the **growth factor = 0**, then the epidemic is over.

I am still very skeptical that these numbers are an accurate description of the current situation however. I feel like I have to explain an apparent contradiction here:

Why is it that back in March I seemed to trust the numbers when I was saying that the virus was spreading

exponentially, but now I seem to distrust the numbers when they say that the infection rate is finally levelling off? Am I just a pessimist regardless of what the evidence says?

Last update: 2020/04/12 09:34

The quick answer is no. The way evidence works is not symmetrical. Imagine you think there's a ball hidden in the room:

- If you find it, you can, with 100% certainty, say that there was a ball in the room.
- If you don't find it, you can't say anything with 100% certainty. Maybe there isn't one, but maybe there is and you just didn't find it.

So back in March, the reported cases grew exponentially, so I could say with 100% certainty that the virus spreading exponentially. Now, the reported cases seem to be growing linearly (the curve is flattening). There are two possible explanations for this:

- 1. The infection is actually flattening out (I really hope and wish this is the case).
- 2. The amount of testing we do is insufficient and we are not recording the actual spread of the virus (I suspect this is the case).
