Receivers

There are three main characteristics of a receiver: sensitivity, selectivity, and stability.

Sensitivity

A signal is always accompanied by some sort of noise, and very roughly speaking, if the signal is stronger than the noise, then it can be heard. To quantify this, we use a term called 🧐 [Signal-to-Noise Ratio](#) (SNR or S/N):

$$\text{SNR} = \frac{\text{Signal}}{\text{Noise}}$$

Since SNR is a ratio:

- If $\text{SNR} > 1$, then the signal is stronger than the noise.
- If $\text{SNR} = 1$, then the signal and the noise have the same strength.
- If $\text{SNR} < 1$, then the noise is stronger than the signal.

Like other ratios, we often express SNR in [decibel](#) so that:

- If $\text{SNR} > 0 \text{ dB}$, then the signal is stronger than the noise.
- If $\text{SNR} = 0 \text{ dB}$, then the signal and the noise have the same strength.
- If $\text{SNR} < 0 \text{ dB}$, then the noise is stronger than the signal.

Now back to the receiver. The sensitivity of a receiver is its ability to pick out weak signals from the noise. That is, it indicates how faint an input signal can be and still be successfully received by the receiver.

For example, here's the specs sheet from the IC-7300:

For example, a receiver with a sensitivity of -123 dBm can pick out a signal of 0.0000000000005 mW.¹⁾

Selectivity

Recall from the [intro section](#) that radio signals always have some width. That is, depending on the type, radio signals can take a different amount of space on the radio spectrum.

Now back to the receiver. The selectivity of a receiver is its ability to pass only the signal of interest and reject everything else.

Stability

Transmitters

Questions

- B-003-009-001 → B-003-008-006

¹⁾

$$-123 \text{ dBm} = 10^{-12.3} \text{ mW} \approx 5 \times 10^{-13} \text{ mW}$$
